Electromagnetic catapult energy storage principle

Overview

How much electricity does an electromagnetic catapult use?

The same energy is then used to return the carriage to its starting position. An electromagnetic catapult can launch every 45 seconds. Each three-second launch can consume as much as 100 million watts of electricity, about as much as a small town uses in the same amount of time.

Can electromagnetic catapult technology be used to launch aircraft?

Electromagnetic catapult technology already has the ability to launch any aircraft now in the Navy inventory and any the Navy has ordered. With the new launch system's potential to achieve acceleration forces reaching 14 Gs, human endurance may be one of the few limitations it faces.

Do catapults store potential energy?

Catapults store potential energy in the arm until you release it. This is called potential elastic energy. Potential energy is stored in elastic, like a rubber band, when it is stretched.

What is the potential energy in a catapult?

In a catapult, potential energy is stored as potential elastic energy in the stretched ropes and rubber bands and in the bent and flexed lever arm of wood or plastic. This energy is called potential energy because it represents the energy an object has due to its position or configuration, in this case, the position of the stretched ropes, rubber bands, and bent lever arm.

Will EMALS be the first catapult to use electro-magnetics to launch manned aircraft?

When complete in 2008, it will be the first catapult to use electro-magnetics to launch manned aircraft. As the Navy's project manager for the Electromagnetic Aircraft Launch System (EMALS), Sulich's task is to move the newest catapult technology from development at the research facility to ships

at sea.

What is a shipboard electromagnetic catapult?

Shipboard electromagnetic catapults will be based on larger linear induction motors, made up of three main parts: two 300-foot-long stationary beams, or stators, spaced a couple of inches apart, and a 20-foot-long carriage, or shuttle, that is sandwiched between the two beams and can slide back and forth along their lengths.
