# **Energy storage substances in subcutaneous tissue**

## Overview

---

One of the primary purposes of subcutaneous adipose tissue is to serve as the body's energy depot. When caloric intake exceeds immediate energy needs, the body converts the excess into lipids, which are then stored within the adipocytes. What is the role of subcutaneous adipose tissue?

International Journal of Obesity 38, 1019-1026 (2014) Cite this article  
Subcutaneous adipose tissue represents about 85% of all body fat. Its major metabolic role is the regulated storage and mobilization of lipid energy.

Why is subcutaneous WAT important?

Thus, more than any other depot, subcutaneous WAT represents a physiological buffer for excess energy intake during times of limited energy expenditure. Subcutaneous WAT acts as a metabolic "sink" for excess lipid storage (14).

What is a healthy subcutaneous tissue?

Healthy subcutaneous tissue can effectively store excess fatty acids, preventing them from accumulating in other tissues like the liver and muscle where they can cause dysfunction. This capacity to safely "buffer" lipids is a protective metabolic function. It contributes to maintaining insulin sensitivity and overall metabolic stability.

Why is subcutaneous fat a good source of energy?

Because it is a ready source of energy, subcutaneous fat has a very rich blood supply. It also plays a part in temperature regulation. Small arteries supply two plexuses (Young et al. 2006). The more superficial is the subpapillary plexus lying in the dermis close to the hypodermis.

How does brown adipose tissue store energy?

Brown adipose tissue also stores energy in lipid form, but more regularly produces heat by oxidizing fatty acids within the adipocyte, rather than

supplying free fatty acids for use by other cell types [2, 4, 5]. Brown fat derives its color from extensive vascularization and the presence of many densely packed mitochondria.

What is subcutaneous adipose tissue (sat)?

Abstract Subcutaneous adipose tissue (SAT) is the deepest component of the three-layered cutaneous integument.
