No energy storage in capacitor after switching

Overview

How do switch mode power supplies solve the half energy loss problem in the charging of a capacitor?

If we charge a capacitor C with a DC source of voltage V , the energy stored in the capacitor is $\frac{1}{2}CV^2$ and the energy wasted in wires is also $\frac{1}{2}CV^2$. Many videos say that SMPS minimizes this cleverly by.

How do switch mode power supplies solve the half energy loss problem in the charging of a capacitor?

If we charge a capacitor C with a DC source of voltage V , the energy stored in the capacitor is $\frac{1}{2}CV^2$ and the energy wasted in wires is also $\frac{1}{2}CV^2$. Many videos say that SMPS minimizes this cleverly by.

The initial energy stored in the charged capacitor is: $E_{\text{initial}} = \frac{1}{2} C_1 V^2$ After the switch is closed, the voltage across each capacitor becomes $(V/2)$. The final energy stored in the system is: $E_{\text{final}} = \frac{1}{2} C_1 \left(\frac{V}{2}\right)^2 + \frac{1}{2} C_2 \left(\frac{V}{2}\right)^2$.
