Interest in novel energy storage and conversion methods has prompted a broad interest in potential applications of conductive, complex materials such as graphene oxide slurries. Investigating the complex rheological, material, and chemical properties of chemically exfoliated graphene oxide.

Interest in novel energy storage and conversion methods has prompted a broad interest in potential applications of conductive, complex materials such as graphene oxide slurries. Investigating the complex rheological, material, and chemical properties of chemically exfoliated graphene oxide.

The rheological behavior of lithium-ion battery slurries composed of LiFePO<sub>4</sub> and graphite with two polyvinylidene fluoride (PVDF) binders, HSV900 and KF1100, was investigated using steady-state, transient shear flow, creep, and dynamic oscillatory shear experiments. The study revealed that the. Are Lib cathode slurries rheologically stable?

Numerous scholars have studied the rheological behavior of slurries from different approaches. The colloidal stability of LIB cathode slurries was systematically investigated by Bauer et al., 6 who demonstrated that high-molecular-weight PVDF binder facilitates gel formation in nanoscale LiFePO<sub>4</sub> systems.

Can solar energy storage be used for a large latent heat?

A partial miscibility of both components was observed, but they form independent domains at a microscale level, which allows to obtain blends with high crystallinity and, therefore, with a large latent heat to be used for solar energy storage applications.

Do binders affect rheological performance of lithium iron phosphate slurries?

A comparative analysis of these binders in both lithium iron phosphate (LFP)- and graphite-based slurries provides critical insights into binder-induced rheological mechanisms, highlighting the pivotal role of binder selection in optimizing fabrication processes and enhancing the electrochemical

performance of LIB electrodes.

Which rheological instrument was used for rheological experiments?

All rheological measurements were performed with an ARESG2 strain-controlled rheometer from TA Instruments equipped with cup and bob geometry. For rheological experiments 10 mL of the 500 g, and 1000 g graphene oxide suspension in water was loaded into the cup portion of the ARESG2.
