Overview

Superconducting magnetic energy storage (SMES) systems are created by the flow of current in a coil that has been cooled to a temperature below its critical temperature. This use of superconducting coils to store magnetic energy was invented by M. Ferrier in 1970. A typical SMES system includes three parts: superconducting coil, power conditioning system and energy storage system.

What is superconducting magnetic energy storage (SMES)?

Superconducting magnetic energy storage (SMES) systems store energy in the magnetic field created by the flow of direct current in a superconducting coil that has been cryogenically cooled to a temperature below its superconducting critical temperature. This use of superconducting coils to store magnetic energy was invented by M. Ferrier in 1970.

Can superconducting magnetic energy storage systems be used in power systems?

Abstract: Advancement in both superconducting technologies and power electronics led to high temperature superconducting magnetic energy storage systems (SMES) having some excellent performances for use in power systems, such as rapid response (millisecond), high power (multi-MW), high efficiency, and four-quadrant control.

What is a superconducting magnet?

Superconducting magnets are the core components of the system and are able to store current as electromagnetic energy in a lossless manner. The system acts as a bridge between the superconducting magnet and the power grid and is responsible for energy exchange.

When did superconducting magnetic energy storage start?

In the 1980s, breakthroughs in high-temperature superconducting materials led to technological advances. In the 1990s, the rapid expansion of China's power system, power safety became a national priority, and superconducting magnetic energy storage began to be applied because of its superior performance.

How does a superconducting wire work?

The superconducting wire is precisely wound in a toroidal or solenoid geometry, like other common induction devices, to generate the storage magnetic field. As the amount of energy that needs to be stored by the SMES system grows, so must the size and amount of superconducting wire.

How does a superconductor work?

Here the energy is stored by disconnecting the coil from the larger system and then using electromagnetic induction from the magnet to induce a current in the superconducting coil. This coil then preserves the current until the coil is reconnected to the larger system, after which the coil partly or fully discharges.
